Introduction

Impotence, also known as [erectile dysfunction \(ED\)](#), is the inability to maintain or develop an erection necessary for **sexual satisfaction**.

Many men suffer from this problem at some point in their lives.

While some men are not able to get an erection at all, others get an erection that is not sufficient for sexual pleasure.

ED is a medical condition and treating it is essential if normal sexual intercourse is to be resumed.

About Viagra Erection Enhancement drug

Sildenafil citrate, marketed as **Viagra**, which is also same component of the [Generic Viagra is an oral medication used for the treatment of impotence](#).

Viagra is a potent PDE5 inhibitor.

Viagra as drug works by eliminating the PDE that decomposes the cGMP and as a result, the cGMP builds up in the penis and has a larger effect on the arterial walls.

With the enhanced amounts of cGMP, the blood flow to the penis also increases, and this, in turn, enhances the degree of erection.

Studies have revealed that Viagra works in more than 90% of the men.

It helps them develop and maintain an erection long enough for satisfactory sexual intercourse.

However, consider that taking this drug alone does not help men get an erection.

It only works for men who are sexual stimulated.

Why Viagra is sometimes refer to as Sildenafil citrate?

Viagra is many times also referred to as sildenafil citrate because ***Sildenafil is the active ingredient in Viagra that treats impotence.***

It is this ingredient that is responsible for all action in your body.

Sildenafil fits right into the PDE5 enzyme and stops its action of breaking down the cGMP, the presence of which is essential for an erection to take place.

Sildenafil citrate enters the circulation system and streams all through the body.

It joins to the PDE5 chemical in the penis and handicaps a large portion of it.

Thus, when the man turns out to be sexually still, the mind sends the ordinary message to the NANC cells in the penis to deliver nitric oxide of course.

The nitric oxide makes more cGMP, which unwinds and expand the supply routes in the penis.

The penis blows up with blood, and the man gets a full erection.

Who ought not take Viagra?

Viagra is a sheltered medication however it accompanies its offer of issues. Viagra do not use in mix with specific prescriptions.

Viagra should not be combine with nitrate drugs for the treatment of heart problems or chest pain.

Nitrates are find in many recreational drugs such as 'amyl poppers'.

Also, use of Viagra must not be combine with beta blockers or HIV drugs.

Combining Viagra with some drugs can cause a sudden decrease in blood pressure, resulting in heart attacks or fainting.

If you suffer from the following problems, you should not take Viagra without consulting your doctor first.

These include:

Low or high blood pressure

Coronary artery disease

Liver or kidney disease

Ulcers in the stomach

Hemophilia

Retinal disorders

Anaemia or leukaemia

Deformed penis

Lactating mothers

Children below the age of 18 years

In case you have any of these problems, it is better to take your medication in the recommended doses only.

Don't alter your dose of Viagra without consulting your doctor first.
